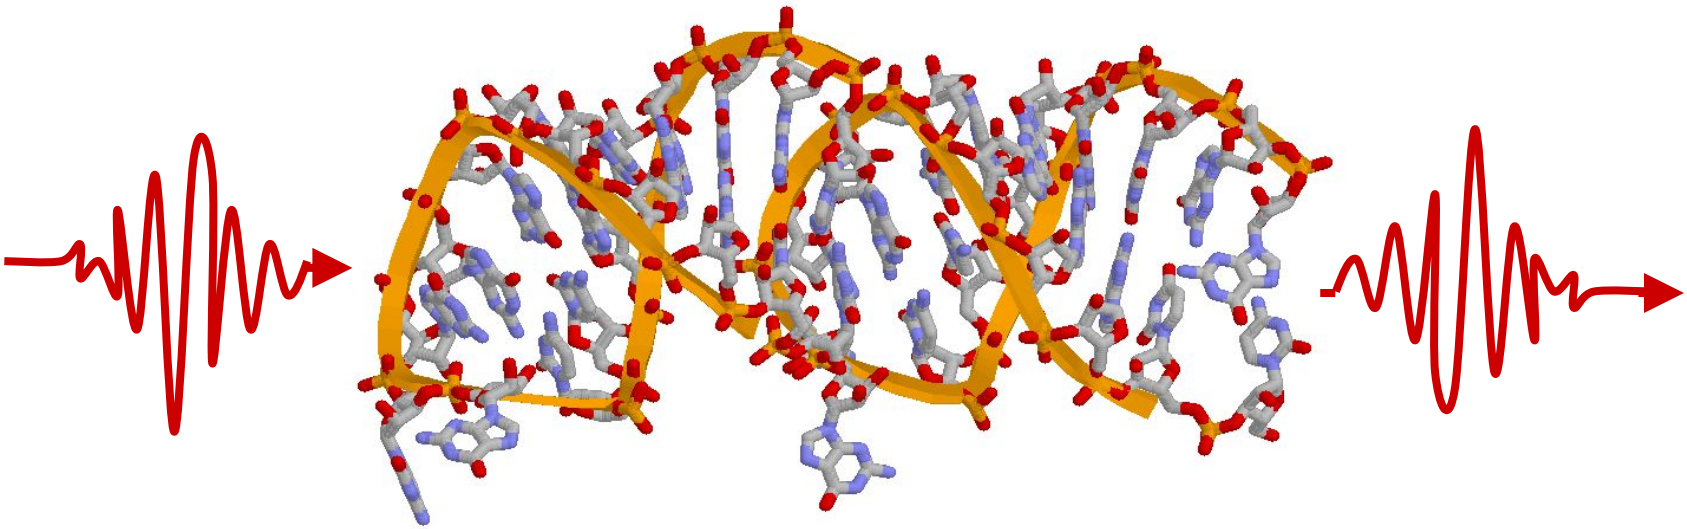
Atomistic DNA simulations: charge transfer in solution and through bio-nano contacts



Thorsten Koslowski
Institut für Physikalische Chemie,
Universität Freiburg, Germany

Why charge transfer ?

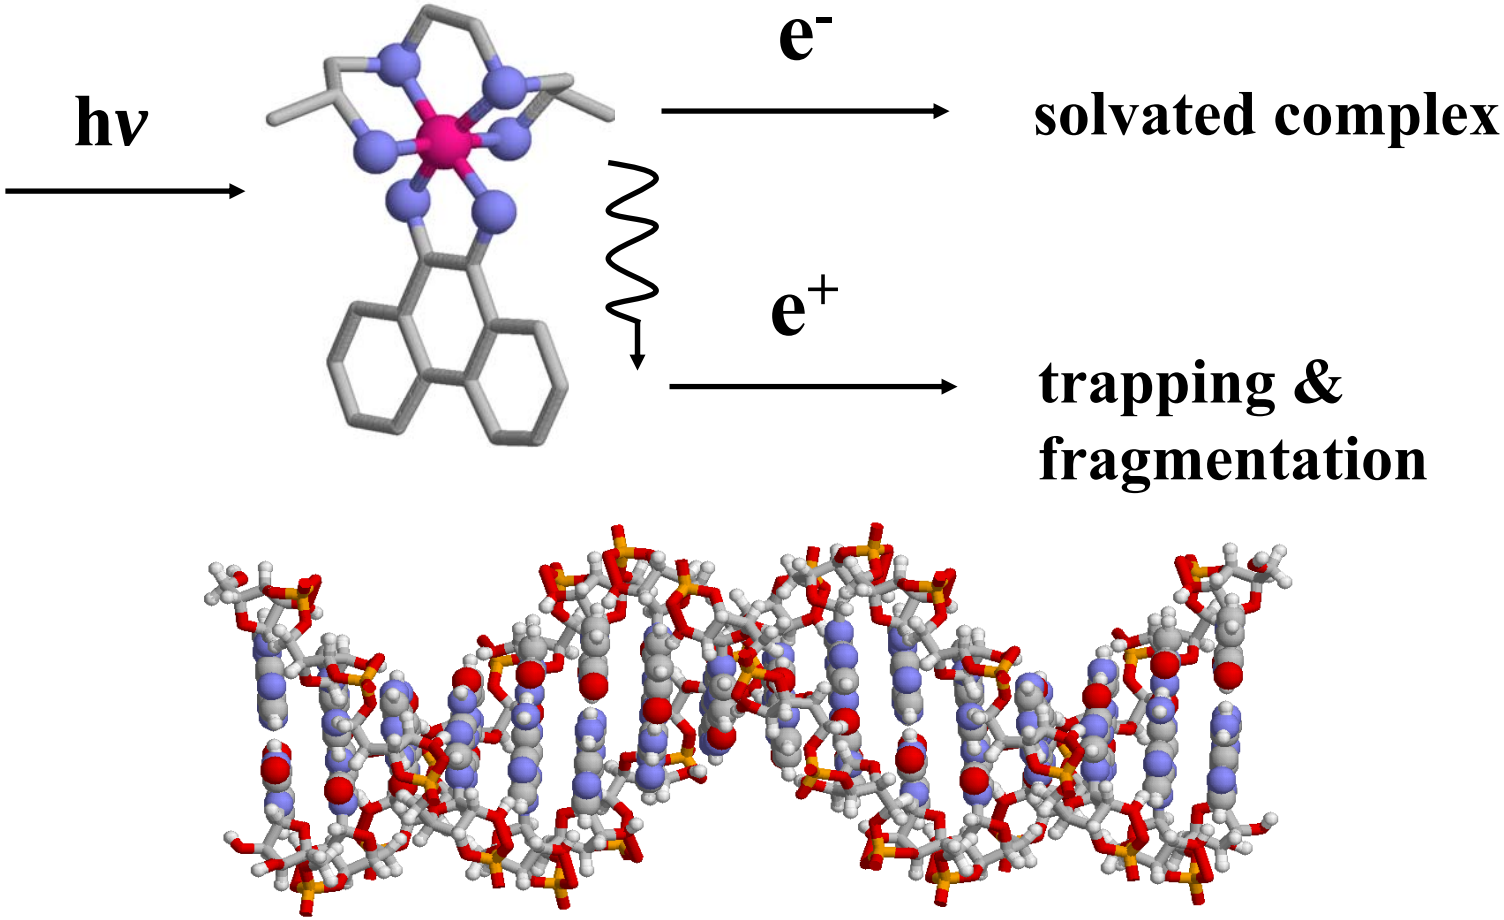
- Fundamental processes of life:
  - photosynthesis
  - respiration
  - oxidative stress
  - mutagenesis
- transport and conductivity
- electrochemistry, corrosion
- nanoelectronics
- (Bio)sensors
- organic photovoltaics

Hölldobler/Wilson

GEO

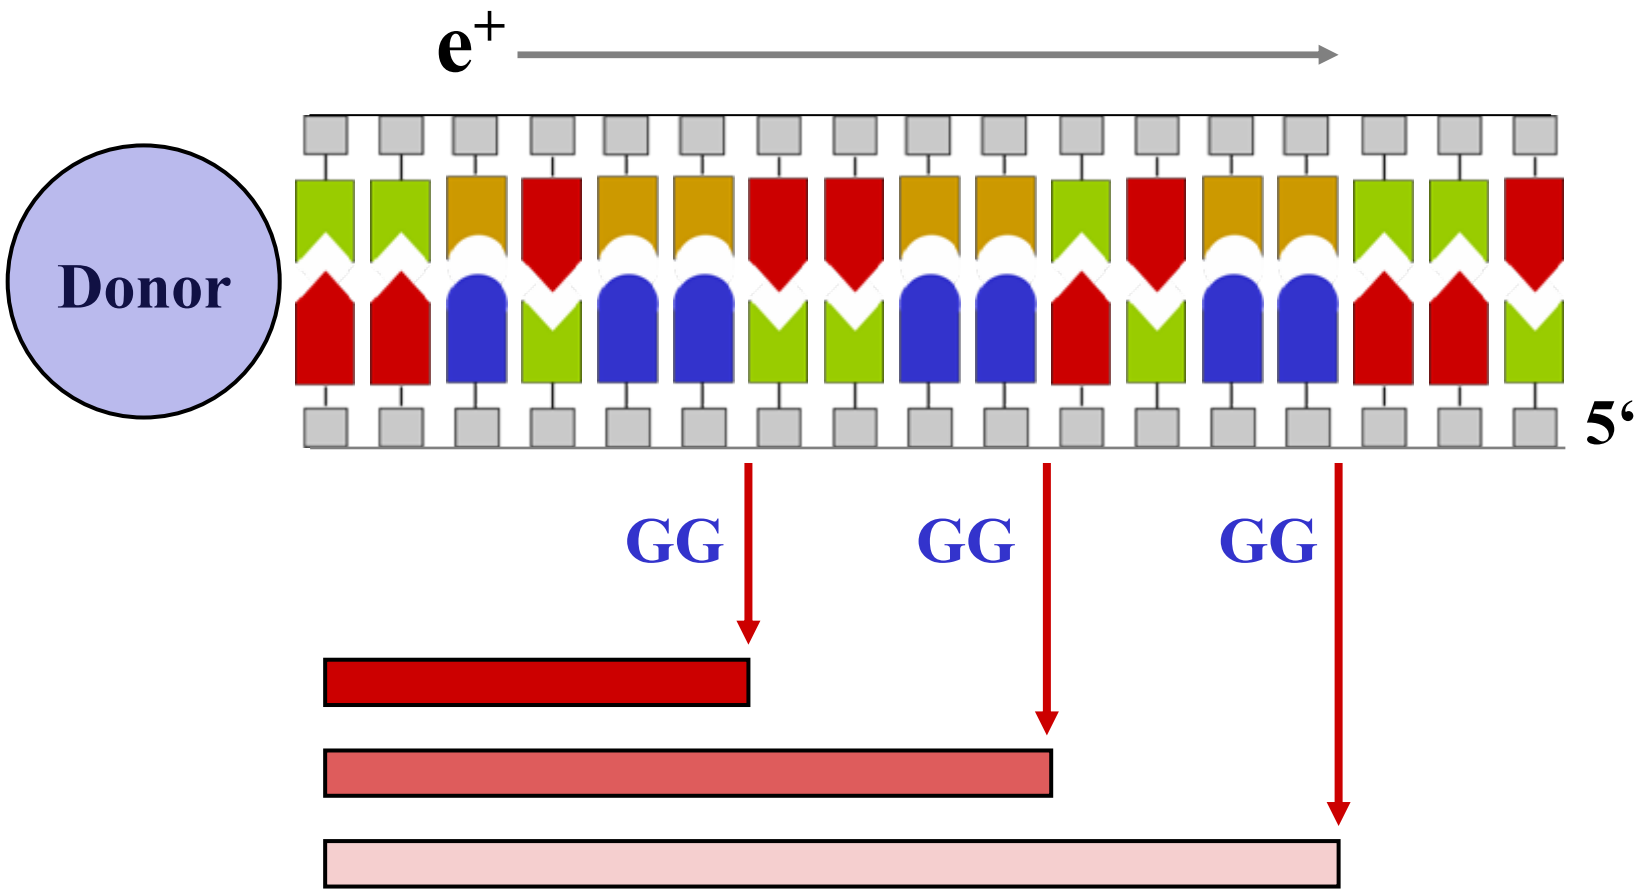
DNA charge transfer experiments

DNA charge transfer experiments in chemistry



Giese, Barton, Michel-Beyerle, Schuster, Carell, Wagenknecht, …

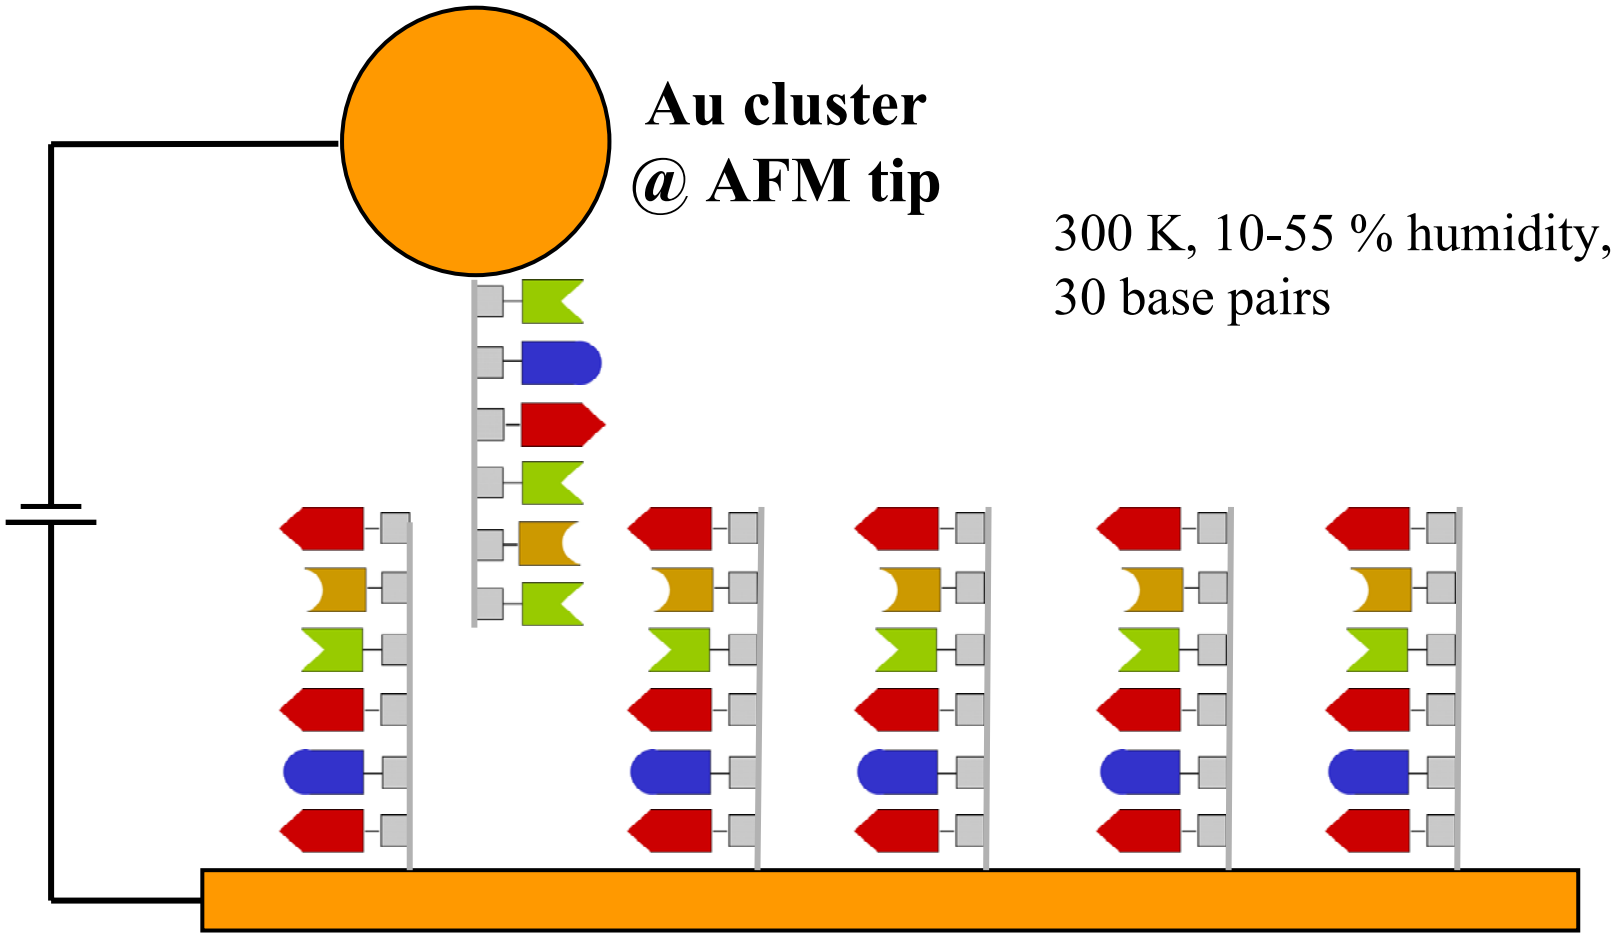
Trapping and fragmentation at multiple G sites



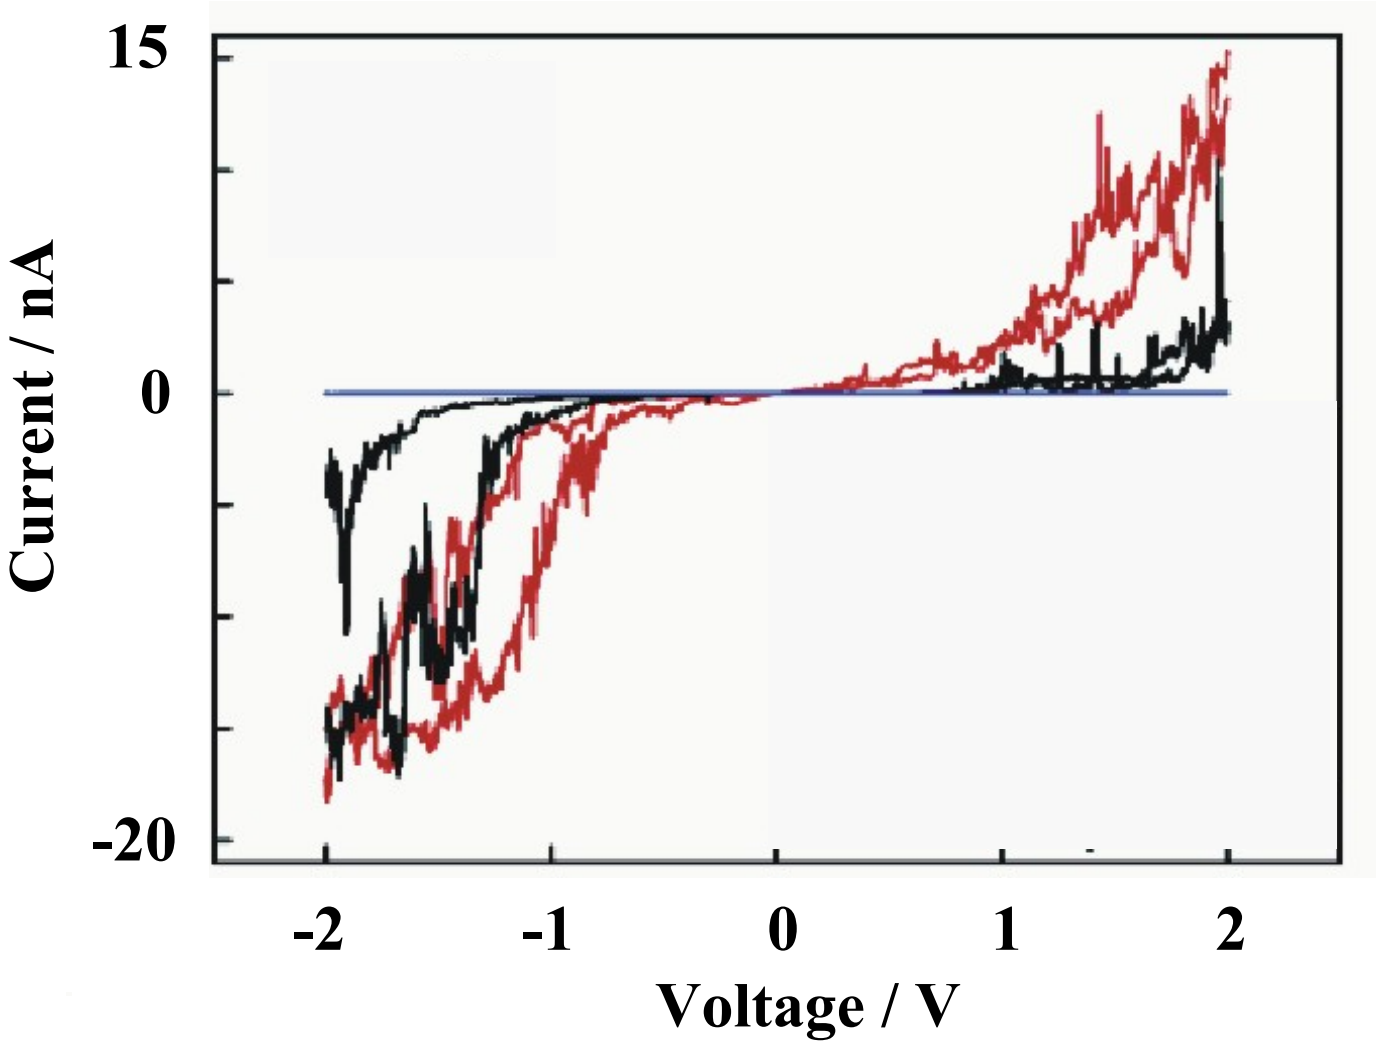
The fragment size distribution reflects the reaction kinetics

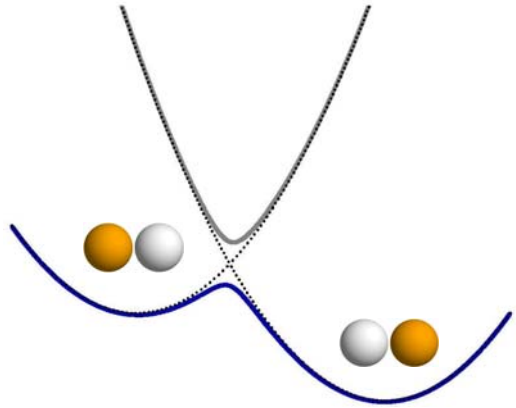
Nanoscopic conductivity setups

e.g. Porath et al., PNAS 102, 11589 (2004)



DNA: metal, semiconductor or insulator ?

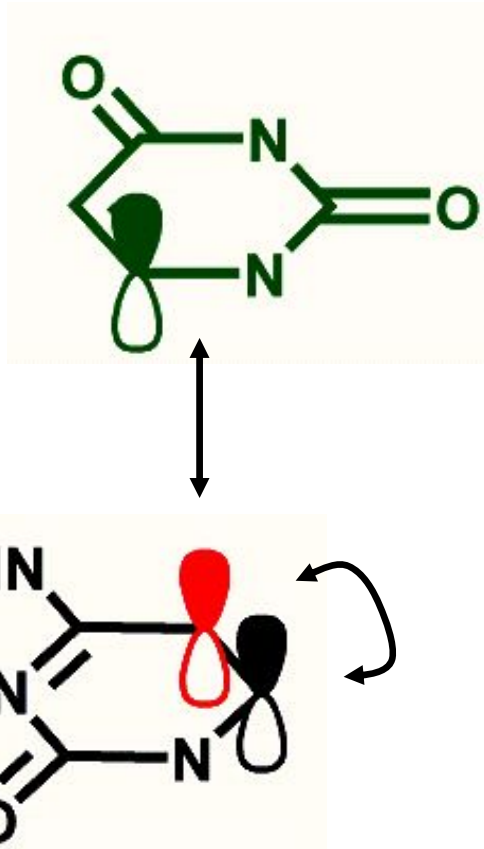




Theory I: model Hamiltonian and variational approach

The model: chemical bond

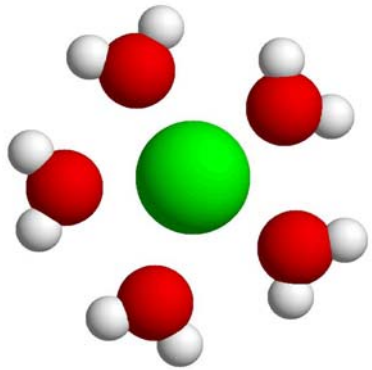
- atomistic LCAO picture
- nucleobase π orbital basis only
- Slater-Koster rules
- chemical specifity (N,C,O)
- *ab initio* DFT parametrization

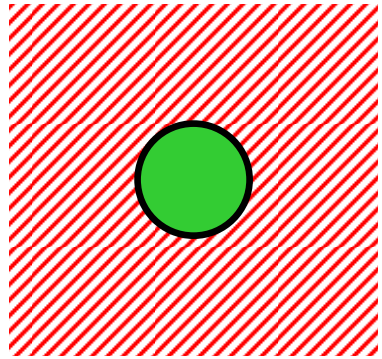


Outer sphere reorganization

solvated ion

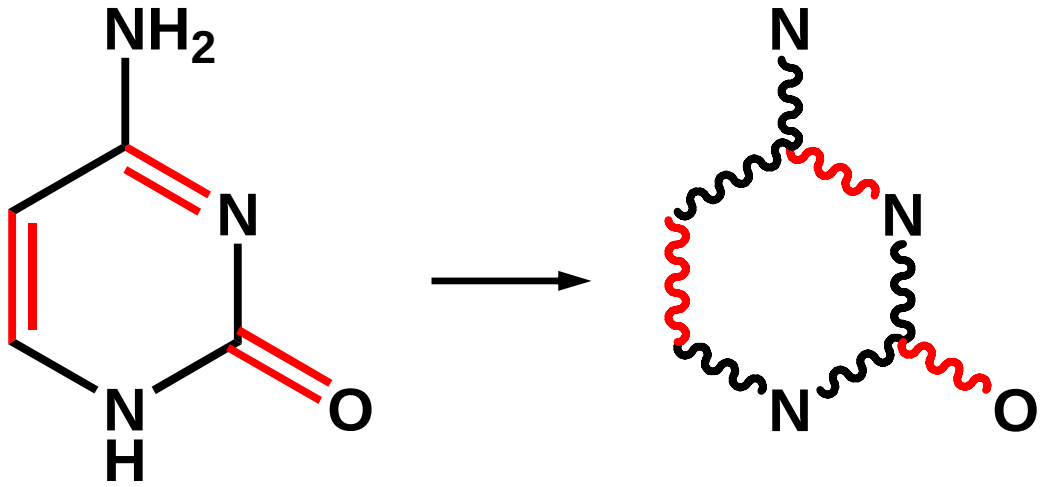
hard sphere in a dielectric continuum





$$\lambda_{out} \simeq \frac{e^2}{4\pi\epsilon_0}\left(\frac{1}{\epsilon_s}-\frac{1}{\epsilon'}\right)\sum_i \frac{\Delta z_i^2}{\sigma_i} = -\sum_i U_i(n_i-\bar{n}_{i,0})^2$$

Inner sphere: Su-Schrieffer-Heeger model



$$\hat{V} = \sum_{\langle ij \rangle} \frac{k}{2} x_{ij}^2 - \sum_{\langle ij \rangle \sigma} [t_0 - \alpha x_{ij}](a_{i\sigma}^\dagger a_{j\sigma} + a_{j\sigma}^\dagger a_{i\sigma})$$

Resulting polaron-transformed electronic mean-field Hamiltonian

less corrections for counting the interactions twice:

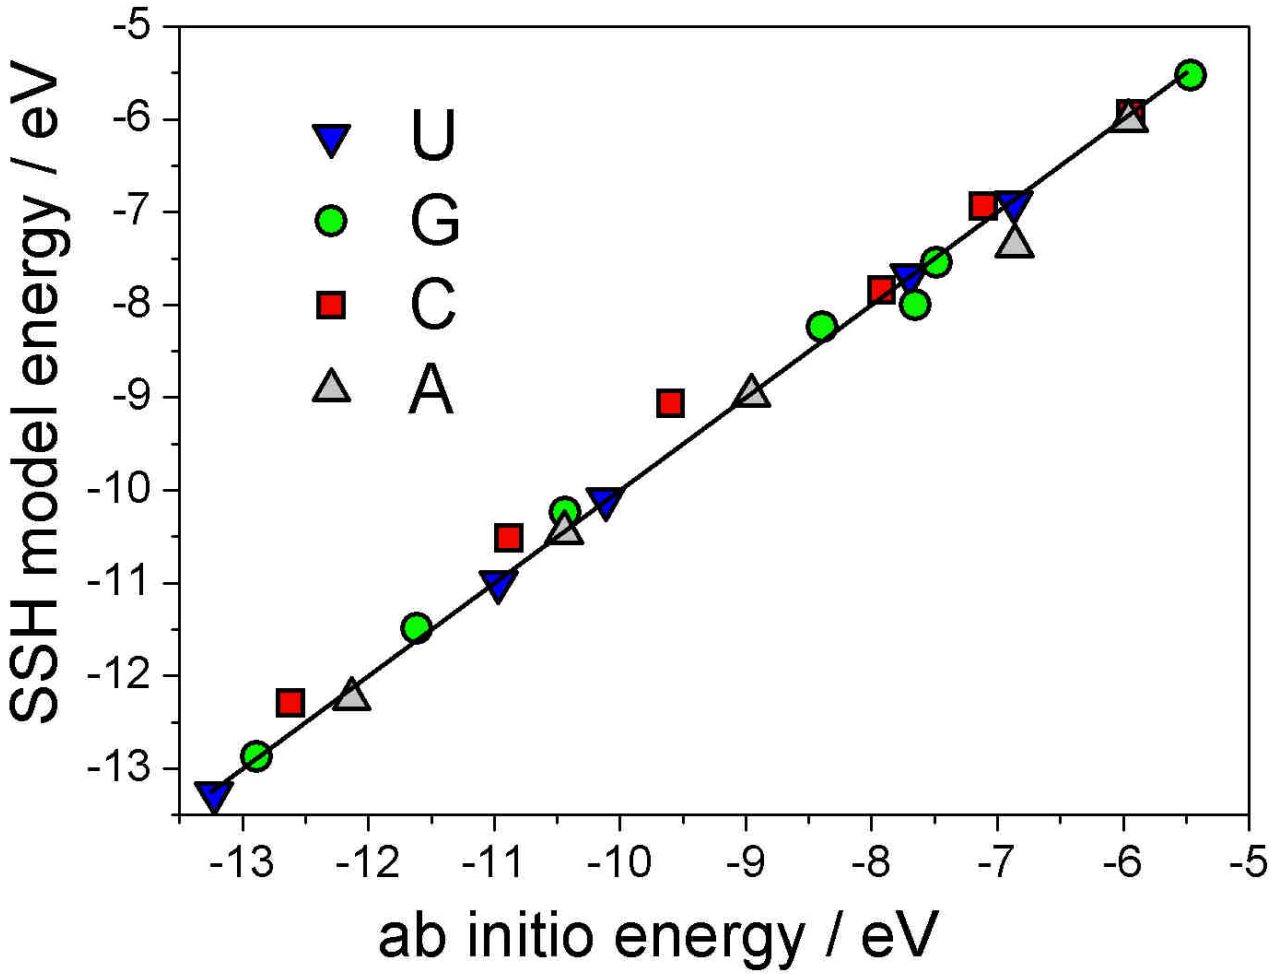
$$\hat{H} = -\sum_{ij}(t_{ij} + 4U_{ij}\bar{n}_{ij})a_i^\dagger a_j - 2\sum_i U_i n_i(\bar{n}_i - \bar{n}_{i,0})$$

chemical bond

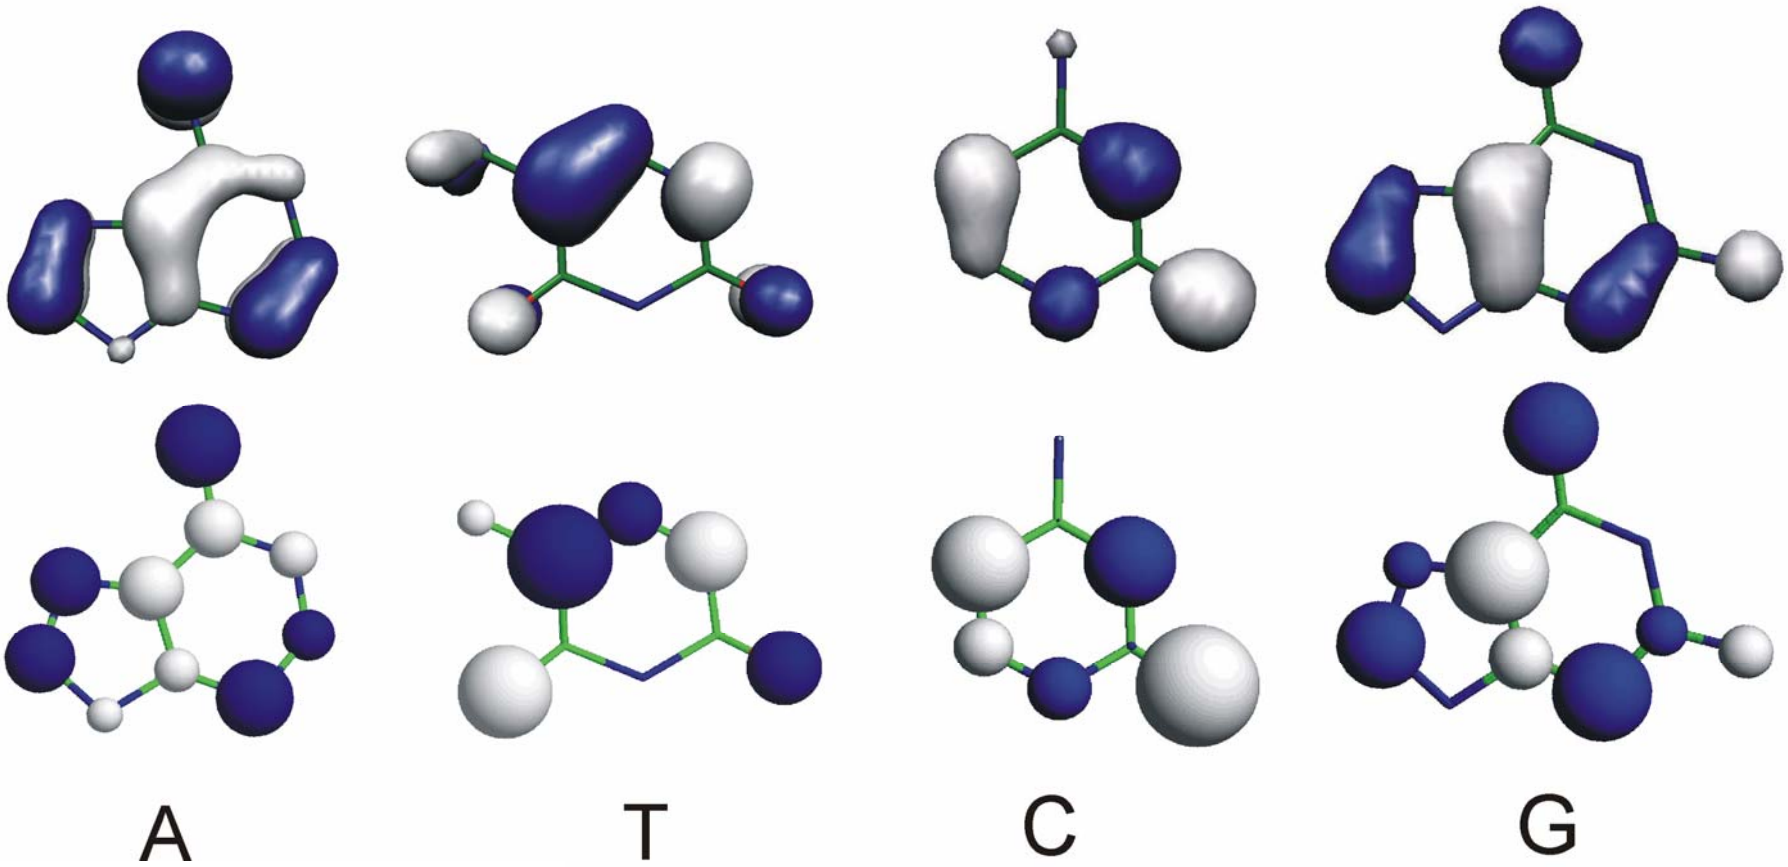
vibronic coupling

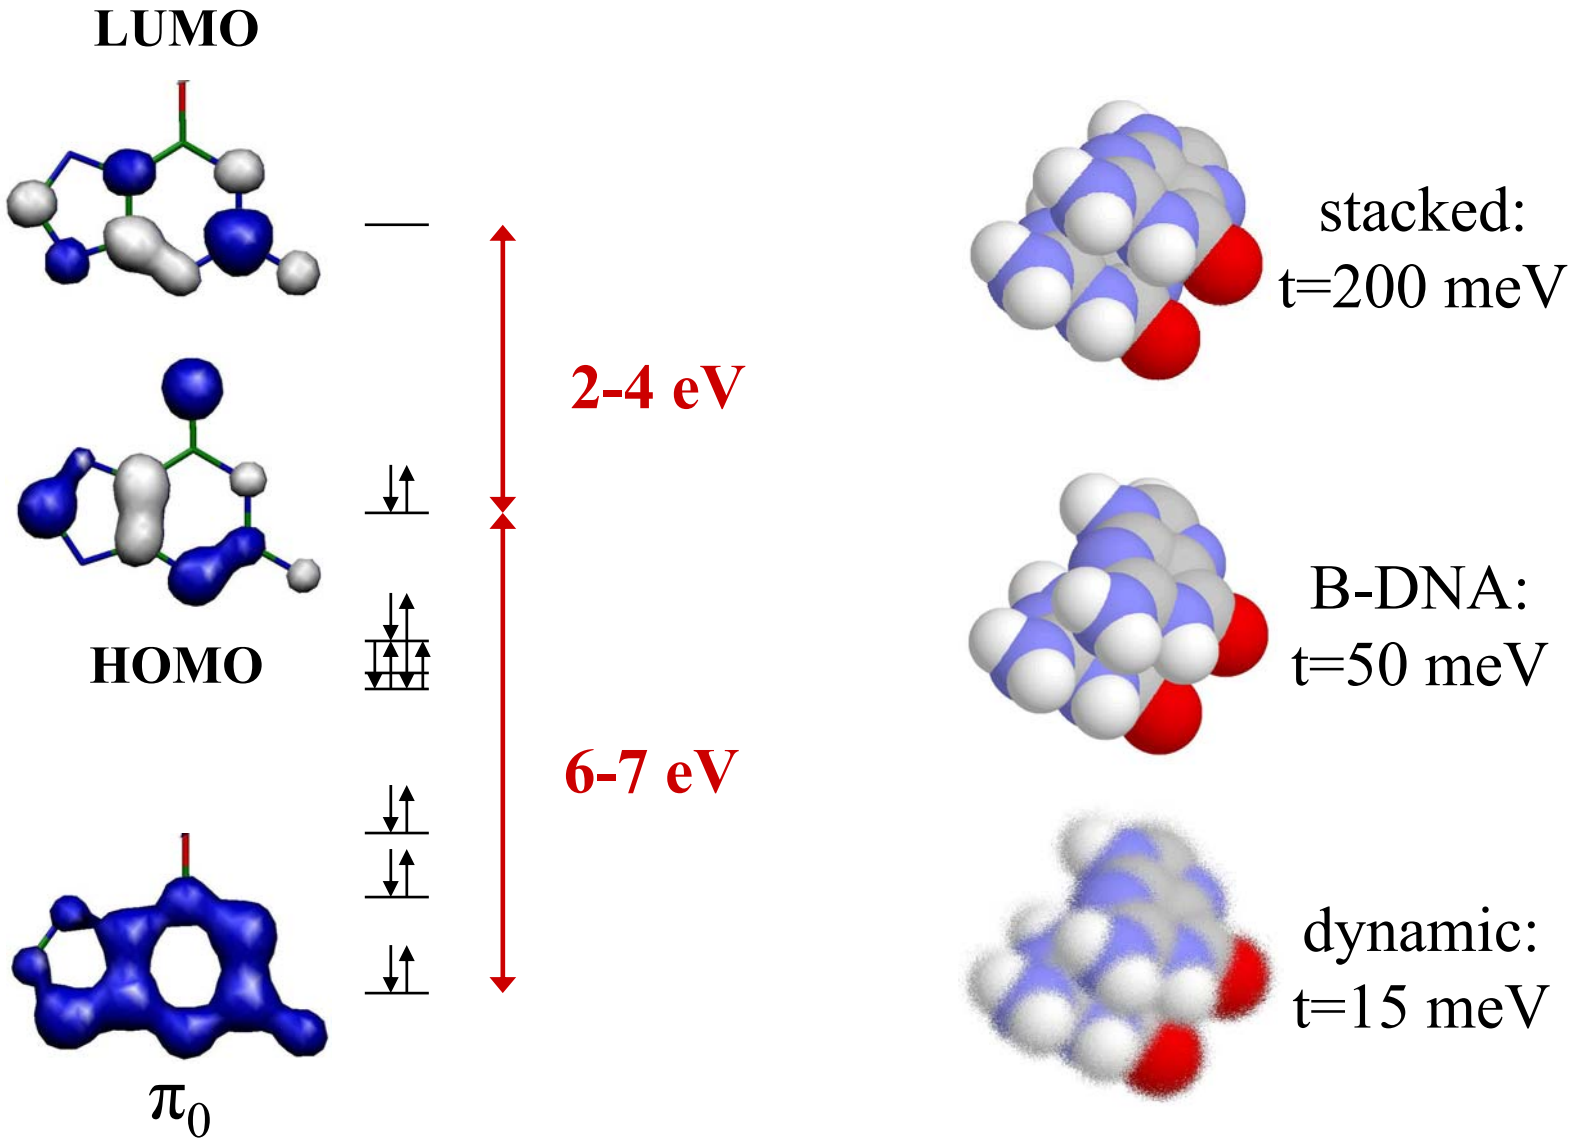
solvent polarization

Parametrization: π orbital energy levels



Test of the parametrization: *ab initio* HOMOs and SSH model HOMO coefficients





intrabase = bonding >> **inter**base = banding

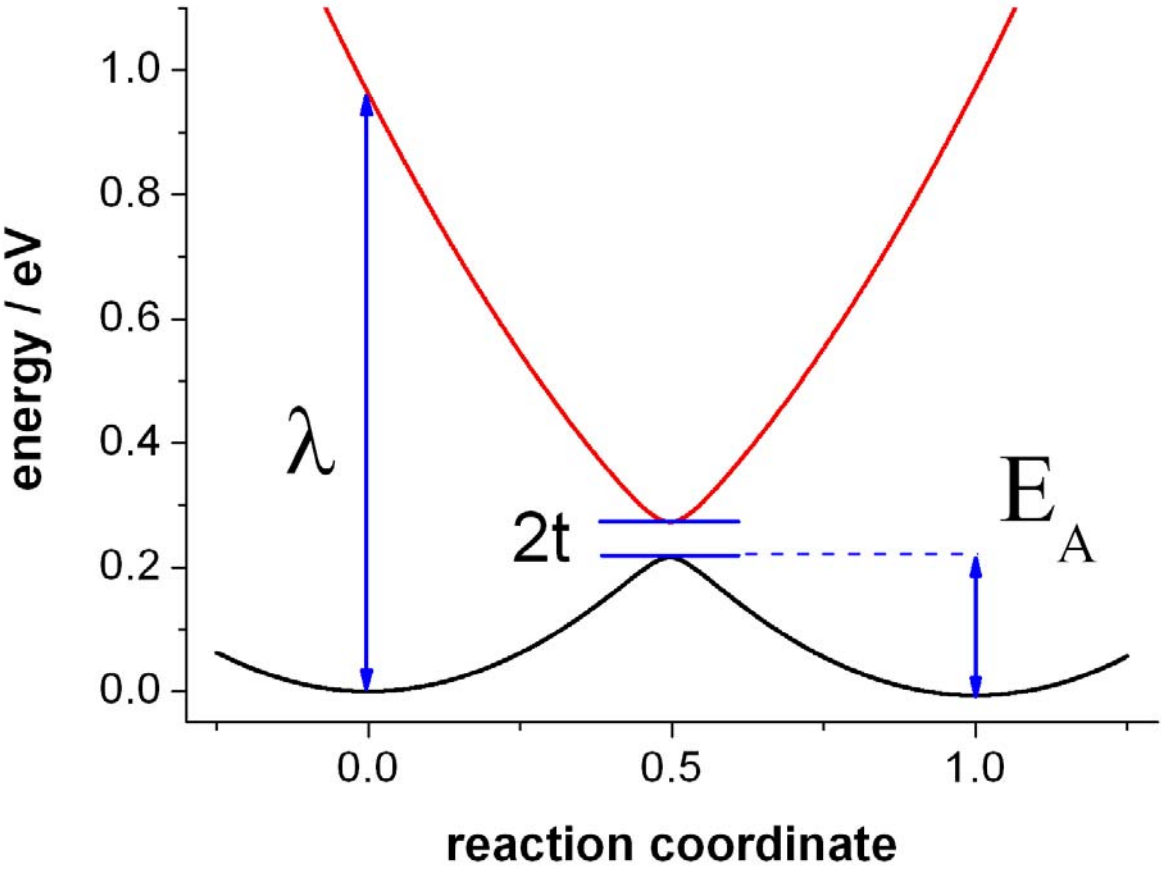
Solving the SSH+U Hamiltonian: energy profile for G-A-G charge transfer



From energies to reaction rates: Marcus‘ theory

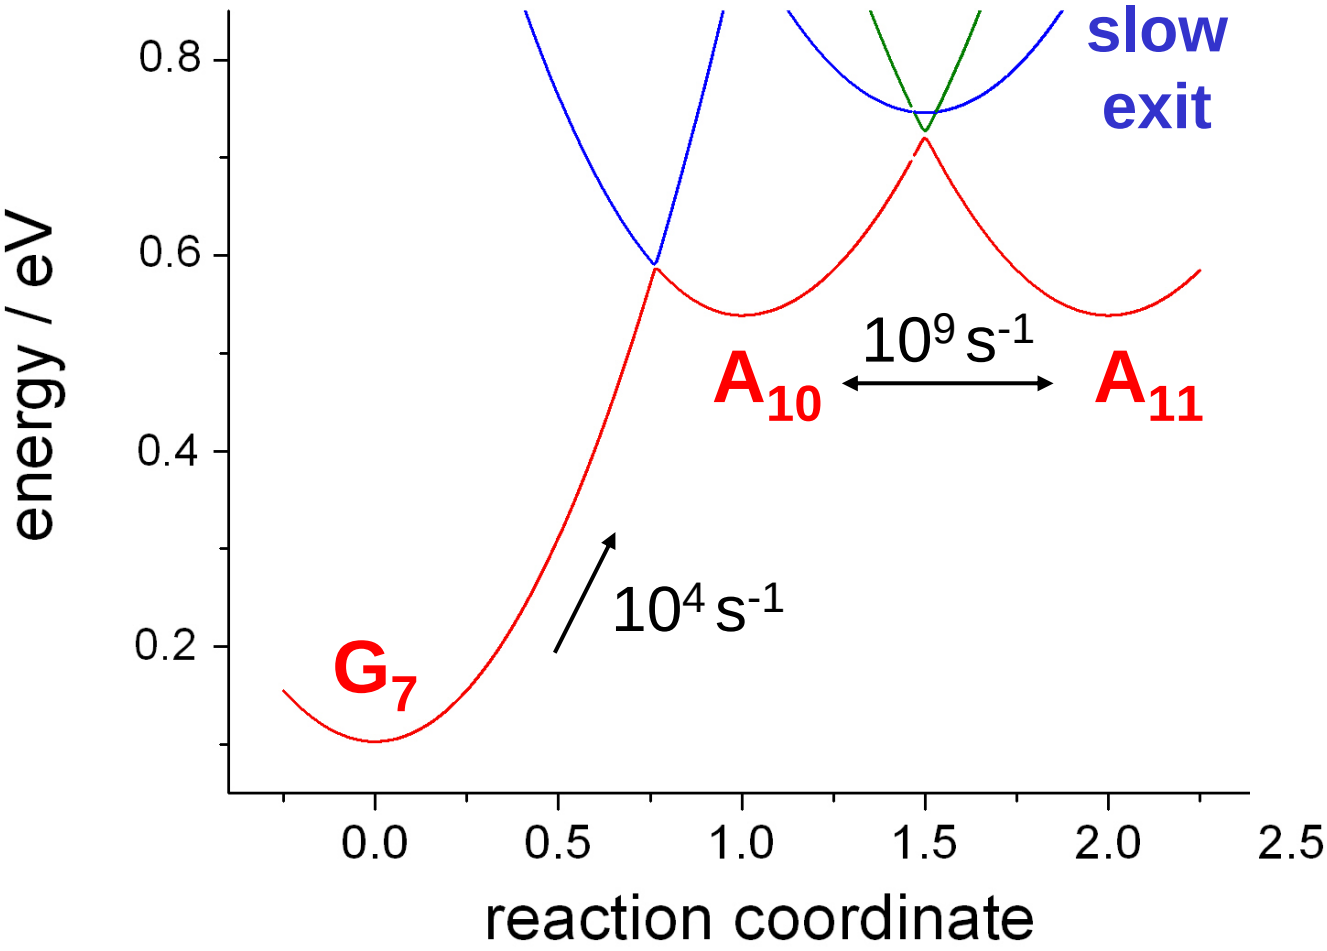
Large *t*, adiabatic, self-exchange:

$$k_{CT} = k_0 \exp\left(-\frac{E_A}{k_B T}\right)$$

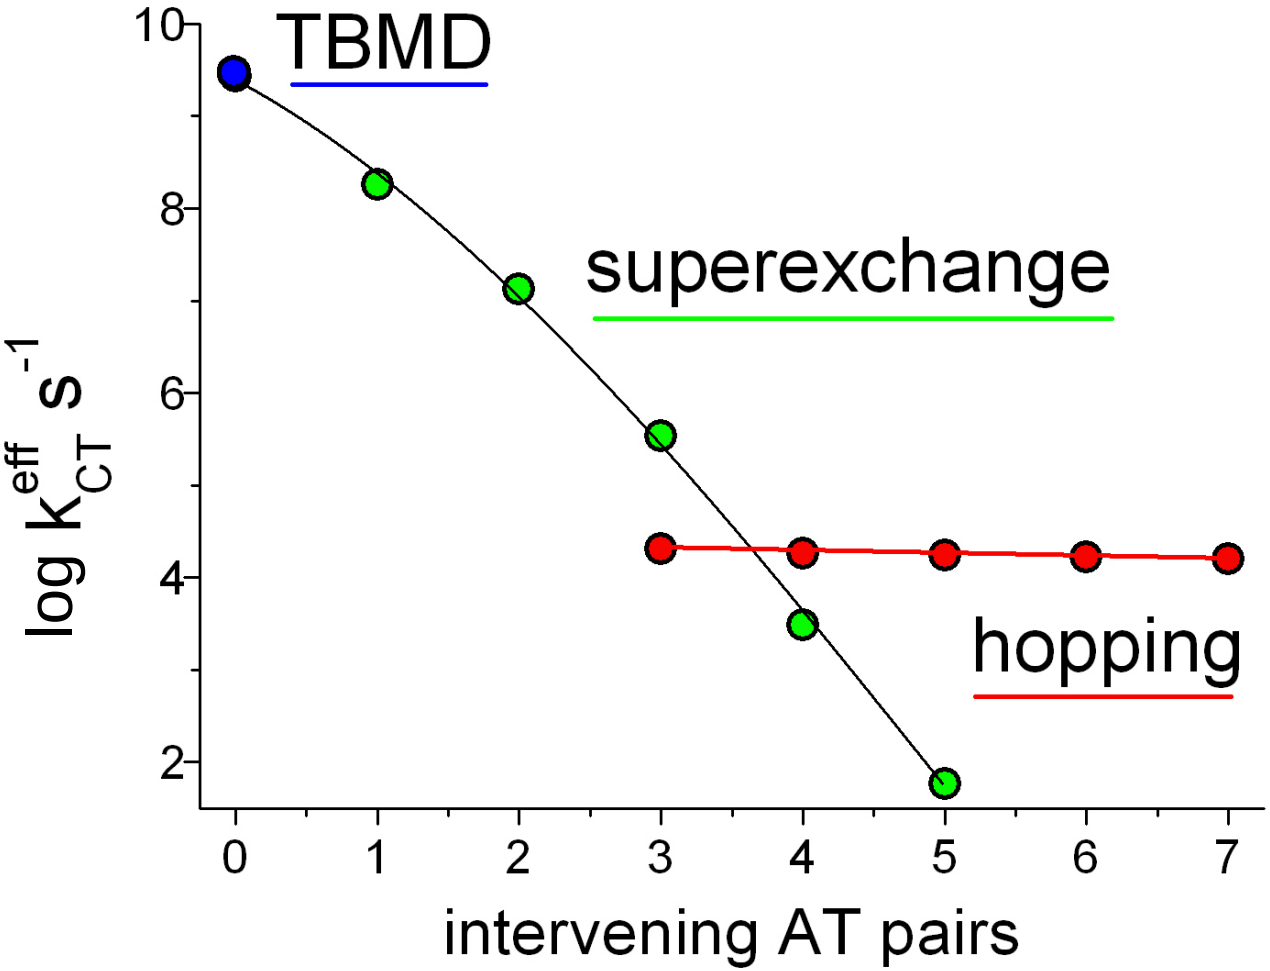
Small *t*, diabatic, self-exchange:

$$k_{CT} = \frac{t^2}{\hbar}\sqrt{\frac{\pi}{\lambda k_B T}} \exp\left(-\frac{E_A}{k_B T}\right)$$

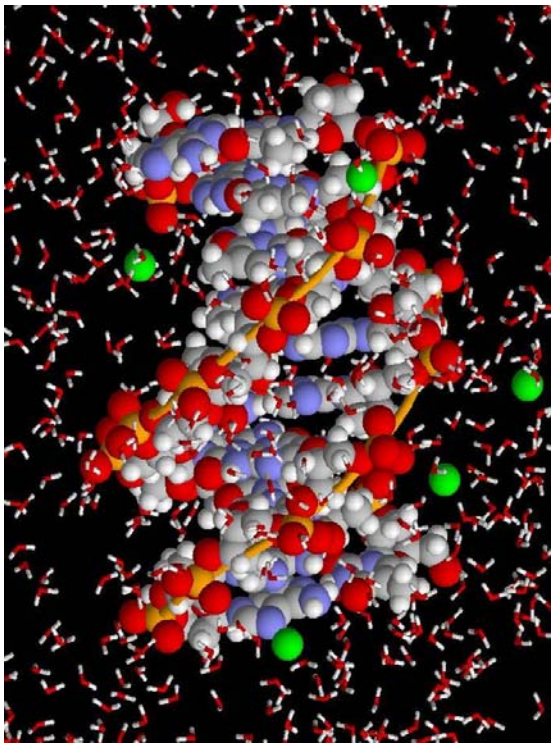
Adenine-adenine hopping



GG charge transfer kinetics for idealized systems

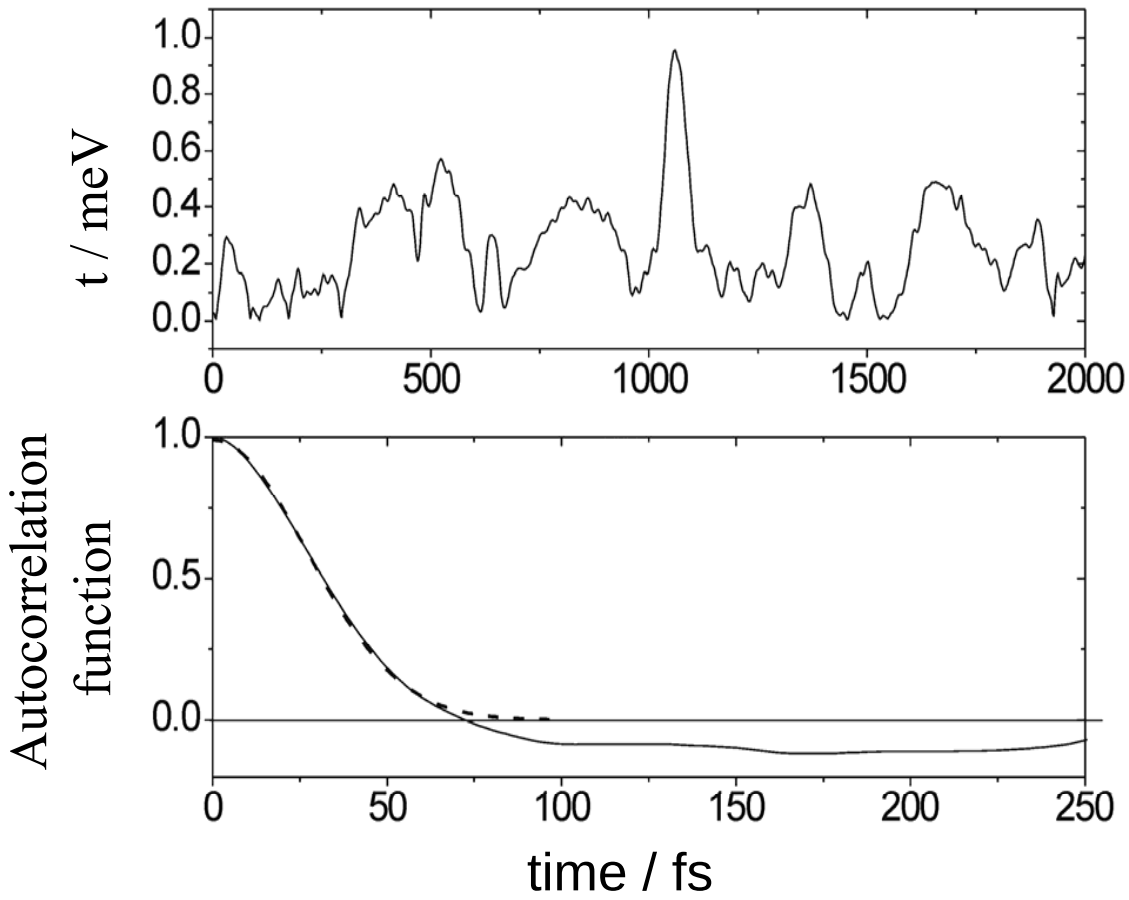


Theory II: MD simulation snapshots as input to the electronic structure theory



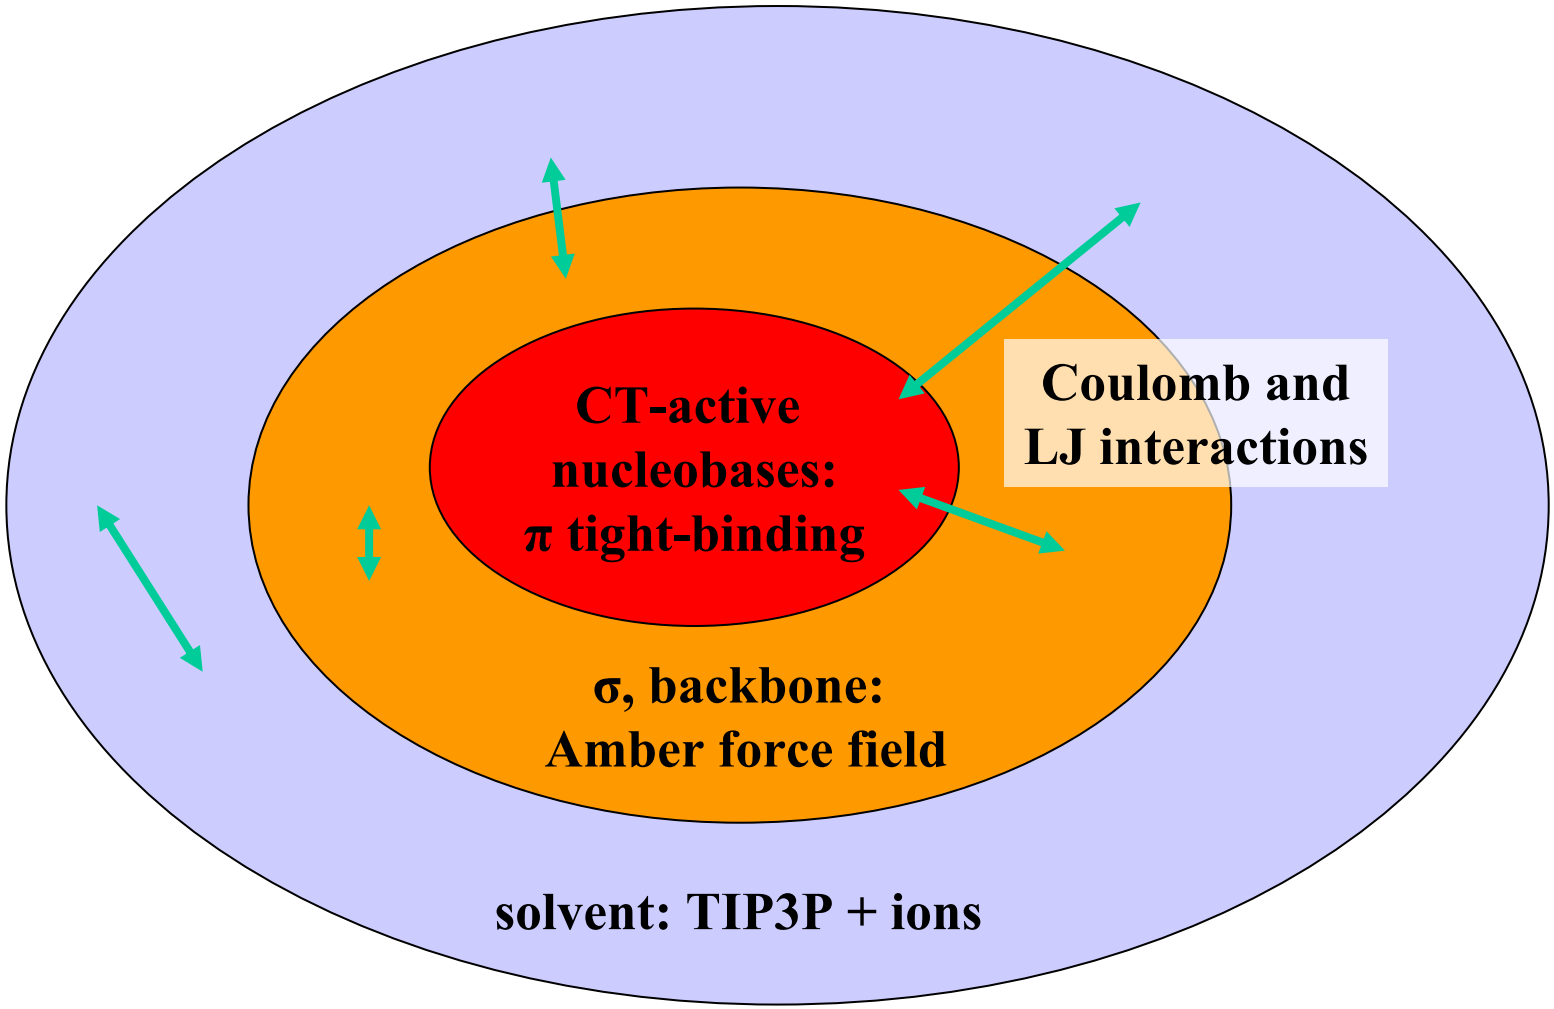
- Amber 8 modelling suite
- TIP3P water model
- 10-14 base pairs
- 16 Å water shell
- Na^+ counterions
- proper equilibration
- 10 ns simulation time
- SSH+U model post-processing

Note: **HOLE ≠ HOMO**

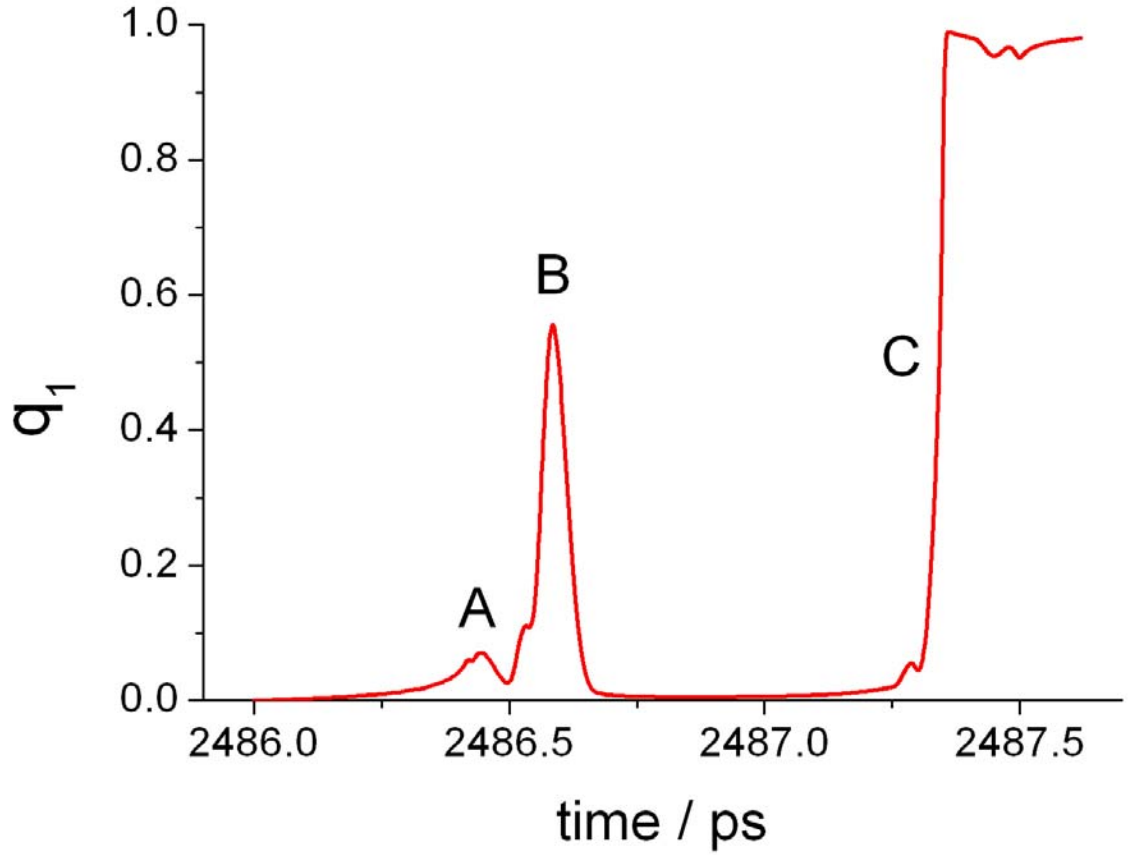


- k_{CT} fluctuates by one order of magnitude
- characteristic autocorrelation time: 30 fs
- elimination of conductivity bottlenecks is faster than CT

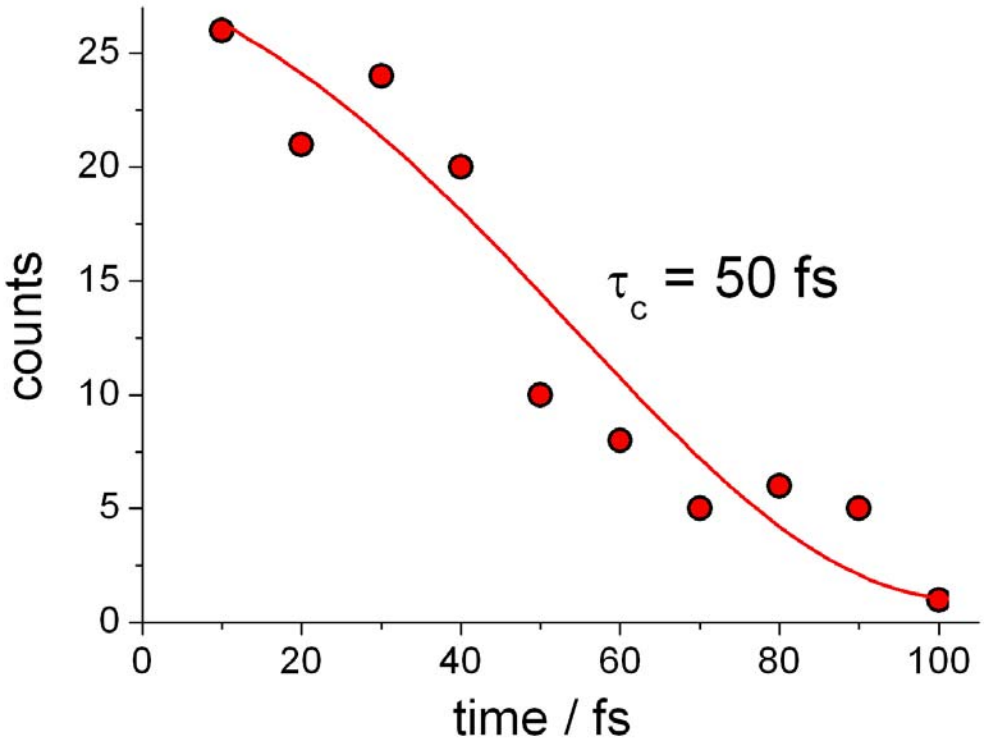
Theory III: direct adiabatic TBMD simulation



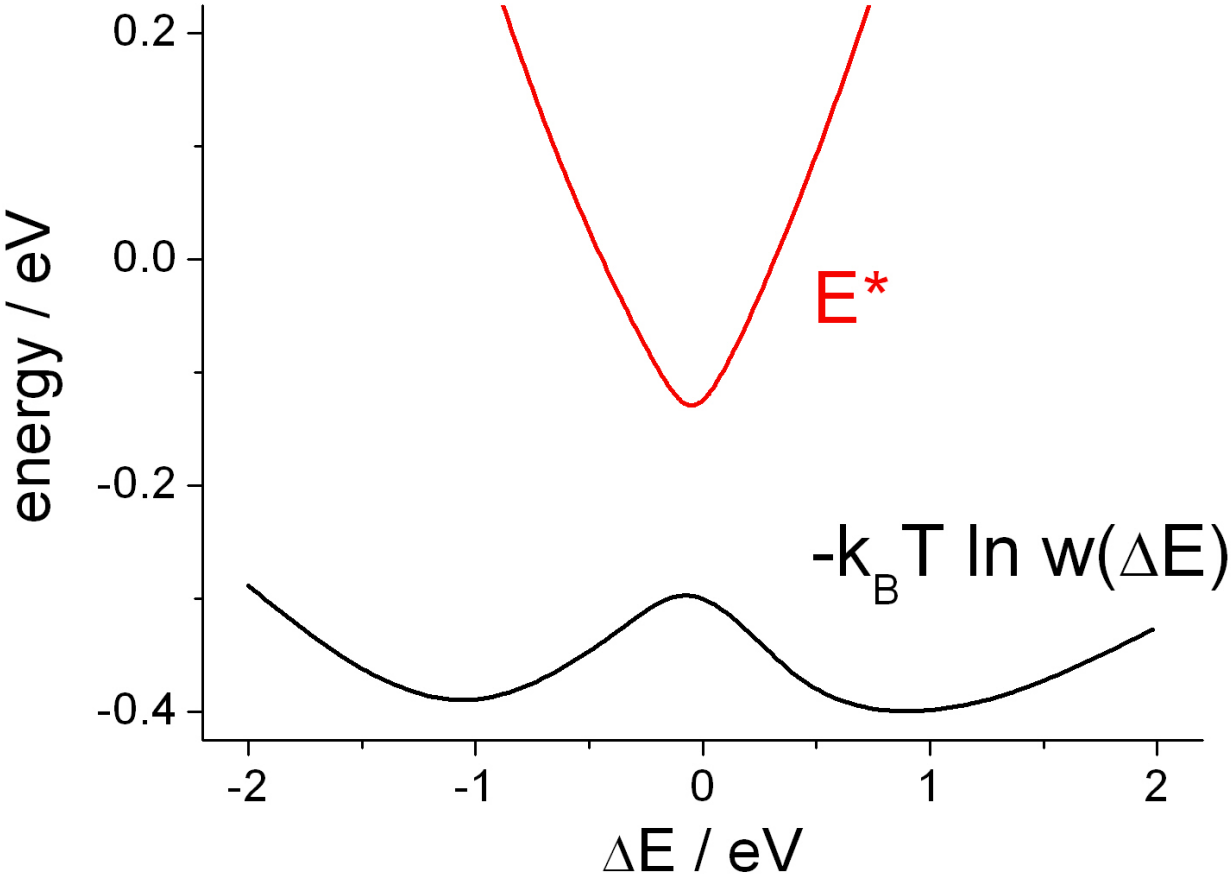
Charge transfer trajectories (A_4AAA_4, A_4GGA_4)
total of 100 ns simulation time per system



Rapid back transfer for 50 % of the hops



Potentials of mean force permit comparison to Marcus‘ theory characteristic energies



Numerical results

CT	AA	GG
t / eV	0.10	0.07
λ / eV	1.08	1.16
E_A / eV	0.09	0.12
k_{CT} / ns^{-1}	4.1	1.3

Theory IV: Transport through DNA nanocontacts

Intersite hopping rates

$$k_{ij} = \frac{t^2}{\hbar}\sqrt{\frac{\pi}{\lambda k_B T}}\exp\left(-\frac{(\Delta G^0 + U_j - U_i + \lambda)^2}{4\lambda k_B T}\right)$$

t, λ, ΔG^0: eSSH-Model; $U_i = E_z\, d_i$ potential at site i

Master equations at stationarity:

$$\sum_{j \neq i}\left[k_{ij}\, p_i (1 - p_j) - k_{ji}\, p_j (1 - p_i)\right] = 0$$

Additional assumptions:

- ideal contact to the gold surface
- fixed number of charges: $Q = \sum p_i$
- smaller reorganization energy compared to solvated systems

Conclusions

- chemically specific, atomistic model of DNA charge transfer
- variational approach, MD+SSH+U, QM/MD
- unified atomistic description of tunneling, hopping, and transport through nanojunctions
