# Local correlation methods

- 1. Question: How can we apply quantum chemical methods for correlation to infinite systems?
- 2. Idea: (Dynamical) electron correlations are short ranged
  - 2.1 Local Ansatz (Stollhoff and Fulde, 1977)
  - 2.2 Local correlation method by Pulay (Pulay, 1983)
    - 2.2.1 Implemented into MOLPRO for molecules (MP2, CCSD(T))
    - 2.2.2 Implemented into CRYSCOR for periodic solids (MP2)
  - 2.3 Method of increments (Stoll, 1992)
- 3. All use localised orbitals for the wavefunction-based correlation calculation

Max-Planck-Institut für Physik komplexer Systeme, Dresden, and (current address) IRL, Wellingt

# The Method of Increments

Decompose the system into a sum of interactions between parts:

$$\epsilon = \Delta \epsilon_1 + \Delta \epsilon_2 + \Delta \epsilon_3 + \dots$$
  
$$\Delta \epsilon_2 = \sum_{ij} \Delta \epsilon_2(i,j)$$
  
$$\Delta \epsilon_2 = \Delta \epsilon_2(1,2) + \Delta \epsilon_2(1,3) + \Delta \epsilon_2(1,4) + \dots$$

 $\Rightarrow$  for metals, use Hartree-Fock energy from CRYSTAL calculations

$$\epsilon_{corr} = \epsilon_{1,corr} + \epsilon_{2,corr} + \epsilon_{3,corr} + \dots$$
  
E(total) =  $E_{HF} + \epsilon_{corr}$ 

 $\Rightarrow$  need well localised orbitals for each correlation increment which should be as close to the true orbitals in the metal as possible

N. Gaston

▲ □ ▶ ▲ □ ▶ ▲

# The Method of Increments

Decompose the system into a sum of interactions between parts:

$$\epsilon = \Delta \epsilon_1 + \Delta \epsilon_2 + \Delta \epsilon_3 + \dots$$

Important properties of the method of increments:

- 1. Correlations short range, but in solids important up to 4th nearest neighbours (at least): usually no chance of simultaneous correlation of all electrons
- 2. The localised orbital groups should be physically reasonable
- 3. Size extensive method i.e. (CCSD(T))

nck-Institut für Physik komplexer Systeme, Dresden, and (current address) IRL, W

・ 同 ト ・ ヨ ト ・ ヨ ト

# The Method of Increments

Applications to date:

- 1. Semiconductors
- 2. Alkali halides and alkali earth oxides
- 3. Transition metal oxides, rare earth oxides and nitrides
- 4. Rare gas crystals
- 5. Polymers, graphite, fullerene
- 6. hydrogen-bound systems: HF and HCl chains

Review article: B. Paulus, Phys. Rep. 428, 1, 2006

N. Gaston

ax-Planck-Institut für Physik komplexer Systeme, Dresden, and (current address) IRL, Wellingtor

Application to metals

# Embedding of finite increments

- 1. Must be done in a consistent way definition of shells (1.7  $a_0$ )
- 2. Separation into "correlation" and "embedding" atoms
- 3. Need to have convergence with respect to:
  - 3.1 Number of "correlation" atoms
  - 3.2 Number of "embedding" atoms

#### ▲ロト ▲□ ▼ ▲目 ▼ ▲目 ▼ → ● → ○ へ ⊙

N. Gaston

lax-Planck-Institut für Physik komplexer Systeme, Dresden, and (current address) IRL, Wellingtor

# Technical details

Definition of the "embedding" atoms

- 1. Large core pseudopotential (only explicit  $s^2$  valence)
- 2. Minimal basis for the valence (4s)/[1s] optimised within large cluster:

Definition of the "correlation" atoms

- 1. Small core pseudopotential (leaving  $s^2 p^6 d^{10} s^2$  electrons)
- augmented TZ (strongly decontracted (10s9p8d3f2g)/[8s7p6d3f2g]) basis set used throughout (Peterson, PP website)
- 3. CCSD(T) calculations of the correlation energy
  - 3.1 Can compare the influence of pure 'valence'  $(s^2)$  correlation and the importance of the underlying *d*-shell

Max-Planck-Institut für Physik komplexer Systeme, Dresden, and (current address) IRL, Well

A (1) > A (2) > A

Application to metals

# Description of metallic character

- 1. Embedding must enable:
  - $1.1\,$  localization of the orbitals
  - $1.2\,$  neutrality of atoms to be correlated
  - 1.3 correct description of virtual space (band gap)
- 2. In metallic clusters the electrons move to the surface of the cluster even for cluster sizes up to 1000 atoms
- 3. This charge is compensated by a positive charge in the center of the cluster
- 4. vanishing gap at the Fermi-level: i.e. the HOMO-LUMO gap has to approach zero

Conclusions

Application to metals

# Simulation of band gap closure

occupied MOunoccupied MO

- 1. Tested (LDA-SVWN level) change of HOMO-LUMO gap
  - 1.1 For the atom, the HOMO-LUMO gap is reduced from 0.125 Hartree to 0.024 Hartree by the embedding
  - 1.2 For the dimer (at NN Mg-Mg distance in solid) the HOMO-LUMO gap is 0.076 Hartree for the free dimer, but closed for embedded dimer.

A (1) > A (1) > A

# Conclusions — method of increments

- can reproduce the binding energy of magnesium, zinc, cadmium, and mercury quantitatively using *ab initio* (CCSD(T)) correlation calculations
- 2. all lattice parameters in good agreement with experiment
- 3. have good convergence of the incremental scheme
- each higher order of increments contributes about an order of magnitude less (4-body same magnitude as ZPVE contribution)

# Conclusions — the group IIB metals

- 1. The equilateral triangle is repulsive in all cases
- 2. The hcp distortion (large c/a) reduces this repulsion
- 3. *d*-correlation adds about 35-50% of the cohesive energy, proportionately more in 3-body
- 4. The change of structure from hcp to rhombohedral for Hg makes the total 3-body contribution more cohesive
- 5. The attractive 3-body interaction for mercury due to close proximity of the *d*-orbitals, caused both by the strong contraction of the Hg-Hg distance relative to the dimer, and the relativistic expansion of the 5*d*-orbitals

<ロト <同ト < 国ト < 国ト

# Conclusions — the c/a anisotropy

- 1. The experimental (anisotropic) minimum comes from the 3-body terms
- 2. This is partly described by *s*-correlation, but overall the wrong slope
- 3. *d*-correlation absolutely vital for total energy and slope of PES
- 4. The two-body terms would give an ideal hcp structure (which remains as a local minimum with 3-body)
- 5. The barrier between the anisotropic and ideal hcp forms of zinc can be estimated to be of the order of 1000 K, well over the melting point of zinc (692.68 K), which may explain why it has never been observed
